Abstract

In the context of meeting the EU energy savings targets and improving the energy efficiency of buildings, this report looks at the competitiveness of the European industry of thermal insulation materials needed for the renovation of Europe’s building stock. Insulation materials could contribute significantly to improving the overall energy efficiency and sustainability of the buildings, especially by reducing the energy losses through the building envelope (walls, roofs, floors, etc.).

Driven by governmental measures to reduce greenhouse gas emissions, improve cost efficiency and adopt regulations on energy efficient buildings, the global demand for thermal insulation materials in building applications is projected to increase at a CAGR of 4.5 % between 2016 and 2027. In the EU the demand for thermal insulation materials is estimated at 3.48 % (2015-2027). Wool minerals (glass and stone wool) and plastic foams (EPS, XPS, PUR) are the most required materials for building insulation.

By analysing the competitive intensity of the global building insulation market and making a SWOT study of the major European companies operating in the insulation materials industrial sector, it is shown that the competitiveness of the European industry of thermal insulation materials in relation to other international competitors is moderate to strong. Six out of the top 10 manufacturers are European companies and some of them are world leaders in production of insulation materials (e.g. stone wool). Overall, the EU is a net exporter of insulation materials. With many other European companies acting at different steps of the value chain of insulation products, the current supply of insulation materials in the EU could be considered as sustainable. Following the adoption of the EU legislation on energy-efficient buildings and in order to meet the increasing insulation requirements needed in buildings, the European industry should strengthen its innovation capability and look further to the development of advanced insulation materials (e.g. super insulating materials (SIM), phase change materials, etc.) for both renovation of the EU building stock as well as construction of ‘near-zero-energy buildings’.
1 Introduction

Buildings consume 40% of the EU’s final energy demand and produce about 35% of all greenhouse emissions. Buildings could have a large energy-savings potential through renovation and upgrading. Under the existing Energy Performance of Buildings Directive, the EU countries must set minimum energy performance requirements for new buildings and for the major renovation of buildings. In this direction, action 5 in the Communication ‘Towards an integrated strategic energy technology (SET) plan: Accelerating the European energy system transformation’ (European Commission, 2015) refers to the ‘Development of new materials and technologies, for the market uptake of energy efficiency solutions for buildings’.

The potential for cost-effective energy savings in buildings can be classified in two main categories:

- Reducing the heat transfer through the building envelopes by improving insulation levels of walls, roofs, floors, windows, etc.;
- Adoption of efficient installations for heating, cooling, ventilation, water heating, lighting and electricity.

Several legislative initiatives stimulate the acceleration of building renovation rates in parallel with construction of new near-zero-energy buildings as measures to increase energy efficiency in buildings.

The EU is a leader in innovation systems and R&D for buildings and this field must remain a priority in order to keep this leadership in the future. Adopting the proposed targets of annually renovating 2% of the whole building stock and 3% of central government buildings (which is doubling of the current renovation rates) as well as the transition to ‘near-zero-energy buildings’ will bring important structural changes in the construction and materials sectors. These sectors will need to anticipate the needs, adapt and develop in order to become more competitive, resource efficient and sustainable.

The successful implementation of the Energy Performance of Buildings Directive would also depend on the effective functioning and competitiveness of construction and material sectors in the EU. It is therefore necessary that high-quality materials are produced and delivered timeously at an appropriate price.
2 Buildings stock in Europe and opportunities for energy savings

Some 160 million buildings were in Europe in 2010 with an overall floor space of about 24 billion m² (Bax et al., 2016). Although the floor space is dominated by residential buildings (75% of the total floor space), their average energy consumption per square metre is much lower compared to non-residential buildings.

The vast majority of the buildings stock dates from before 1990 and about half of the buildings are pre-1960. Today, about 1% of the existing building stock is built new annually, which means it will take 100 years to replace the entire stock. Therefore, the existing older buildings have more potential to contribute to achieving the energy efficiency targets through renovation than the new buildings’ stock. It is estimated that deep renovation of buildings could cut up to 36% of their energy consumption by 2030, while reducing EU energy import dependency, creating growth, innovation and employment, reducing fuel poverty and resulting in more comfortable and healthier buildings (BPIE, 2017).

The competitiveness of the construction companies is an important factor to ensure the sustainability of the sector, as well as associated growth and employment. This sector could contribute significantly to job creation especially in some promising areas such as deep renovation of buildings. It is estimated that approximately 17-19 jobs are created per 1 million EUR invested in improving energy efficiency in buildings (CEU, 2010; Eurace, 2012). The public sector renovation policy at the target rate of 3% per year would result in an average annual employment rate of some 29 000 additional jobs, or some 200 000 person-years of employment by 2020 (Eurace, 2012). Overall, 2 million jobs could be created by 2020 by investing in energy efficiency (European Commission, 2011).

Costs of deep renovation of buildings with substantial energy efficiency benefits range from a few hundred euros/m² up to close to EUR 1 000/m². The latter cost level (EUR 1 000/m²) is close (or beyond) the costs of construction from scratch of a new building in some parts of Europe.

Materials could contribute significantly to reducing energy consumption in buildings and sustain the competitiveness of the construction sector by improving the energy and cost performance in the building envelope (walls, roofs, floors, etc.), windows, mechanical systems as well as on-site renewable generation and thermal systems.

The key focus of this report has been set on the competitive landscape of insulation materials manufacturing in the EU for reducing energy consumption in buildings in connection with the construction sector (Figure 1).

Figure 1. Role of insulation materials to increasing the energy efficiency in buildings
3 Insulation materials for increasing energy efficiency of the building

Insulation materials could highly impact the overall energy efficiency and sustainability of buildings especially by improving the insulation of the building envelope, appliances or other equipment. There is no one material (or technology) that can solve alone the building energy issue. Several insulation materials can be used to reduce energy use in new buildings (near-zero-energy buildings) as well as in retrofitting/refurbishment (renovation) projects. The most common types of materials used for loose-fill insulation of buildings include mineral (stone or glass) wool and plastic foams (e.g. polyurethane, polystyrene, etc.) (Figure 2).

![Figure 2. Types of materials used in thermal insulation of buildings](image)

Although the thermal properties and performance of the traditional building insulation materials have significantly improved over the years, new emerging insulation solutions with similar or higher performances based on biotic renewable or biopolymers are expected to be adopted by the market to a larger extent in the future. Moreover, additional innovative materials (e.g. high reflective nanocoatings, vacuum insulation panels, nanocellular foam, aerogels, phase change materials, advanced insulation foams, etc.) with superior insulation properties, but having higher prices than the conventional solutions, are currently under development, and the EU represents a potential market for them.

Today, the largest market potential for insulation materials in building applications is dominated by those materials which offer the best performance per unit cost, such as mineral (stone and glass) wool and organic fossil fuel-derived plastic foams such as polystyrene and polyurethane (Figure 3).
Inorganic mineral wool has good insulation properties, which are determined by the so-called R-values, and has the highest heat resistance (non-flammable) among the major available materials for building insulations. The R-value determines the effectiveness of an insulating material; the higher the R-value, the greater the insulating effectiveness. While plastic foams are flammable and often associated with health and environmental risks, these foam-based materials show excellent insulation properties. The cost of an insulation material increases with higher R-value. Since the insulation properties (R-value) of materials degrade over time, a cost–benefit analysis of an insulation product has to consider the overall lifetime performance along with its safety aspects. An overall qualitative assessment of the principal properties of most common insulation materials is presented in Figure 3. The green colour indicates good performance and low prices of the materials, while the red colour is an indication of poor properties and high price. Four parameters are used in the matrix, namely: material insulation potential, environmental and safety factors as well as price. The first three parameters denote the "performance" of a given material as indicated in Figure 3.

The obvious winner taking into account the four considered parameters is the glass wool, followed by stone wall.

The insulation materials are used in three major parts of a building that are subject to heat losses, i.e. internal and external walls, floors and roofs. Selection of an insulation material depends on weather conditions and the level of insulation to be included in the building. Wall insulation is the largest application in the building thermal insulation market (by value) with about 47 %, followed by roof (37 %) and floor (15 %) (Visiongain, 2017).

According to IAL Consultants, in 2014 the total European market for thermal insulation products was 7.4 million tonnes (corresponding to 234.6 million m³) of approximate market value of EUR 11.5 billion (IAL, 2015). Commercial and domestic buildings represent the majority of the demand for thermal insulation materials, accounting for 87 %, the remaining 13 % being used in industrial applications.

Glass and stone wool represents 58 % of the European thermal insulation market (Figure 4). This large share of mineral wool is due particularly to the good insulation properties, fire safety and its compatibility with common structural products developed for thermal
insulation. Despite its limited flame retardants properties, expanded polystyrene (EPS) foam is still a common material used for external wall insulation, especially in eastern Europe because of the low price. Polyurethanes (PU) offer some advantages in the context of higher requirements for thermal insulation being less volumetric than other insulation materials for the same insulation efficiency.

**Figure 4.** Thermal insulation market in Europe in 2014, by volume

![Thermal insulation market in Europe in 2014, by volume](image)

*Source: JRC representation with data from IAL, 2015.*

The European thermal insulation market is expected to grow on average at a rate of 2.8% per year until 2019 with higher rates in central and eastern European countries. This will bring the total demand for thermal insulation products in Europe to a total of 269.3 million m³ by 2019 (IAL, 2015).

Wool insulation materials (glass and stone wool) are the most widely used categories for building insulation in the EU and the market is expected to increase by 38% in the period 2015-2025 (Figure 5) (Visiongain, 2017).

**Figure 5.** Thermal insulation market in EU in 2015 and forecast for 2020 and 2025, by value

![Thermal insulation market in EU in 2015 and forecast for 2020 and 2025, by value](image)

*Source: JRC representation with data from Visiongain, 2017.*
Plastic foam materials (i.e. polystyrene, polyurethane, polyisocyanurate and phenolic foam) represent the second segment in terms of market value, accounting for 42% in 2015. It is estimated that plastic foam materials will register a higher growth of 46% by 2025 compared to wool insulation.

Germany, France and Poland are the leading countries in the EU market for thermal insulation materials (Figure 6).

**Figure 6.** Market forecast of thermal insulation materials for representative EU countries. Values represent US million dollars.

Source: JRC representation with data from Visiongain, 2017.

Countries from western Europe represented an important market of insulation materials in buildings, accounting for 30% of the global market in 2015. However, the market in this region is projected to register a slow growth by 2025 as it is quite mature. A higher economic growth of the EU countries and increasing the investments spending will raise the demand for thermal insulation materials.
4 The global market of thermal insulation materials

The global market size of thermal insulation materials for buildings applications was estimated at about USD 22.73 billion in 2015 and is projected to increase at a CAGR of 4.5% between 2016 and 2027, reaching USD 38.69 billion by 2027 (Visiongain, 2017). The increase of demand for thermal insulation materials in building applications will be driven by measures for greenhouse gas emissions reduction, cost efficiency and government regulations on energy efficient buildings.

The EU is the largest market for thermal insulation materials, in terms of value, closely followed by North America (Figure 7).

![Figure 7. Global market forecast for building thermal insulation, by region](source)

In 2015 the value demand in the EU was USD 8 471 million and is expected to reach USD 12 768 million by 2027, at a GAGR of 3.48% (2015-2027) (Visiongain, 2017). The adoption of the EU legislation on energy-efficient buildings is expected to boost the penetration of thermal insulation in the overall building stock and also will increase the amount of insulation needed per building.

Globally, the most required insulation materials to make different kinds of insulation products are based on wool (glass and stone wool) and plastic foams (EPS, XPS, PUR). These materials have different insulating properties and depending on climate conditions they are able to cover a wide range of applications. For example, EPS is mostly used for pitch roof and PUR for internal wall insulations.

The mineral wool insulation segment accounted for just above half of the overall building insulation global market in 2015 (Figure 8). The plastic foams such as EPS, XPS, PUR, etc. accounted for a share of 41% in 2015 and are projected to register the highest growth rate during the next 10 years due to their better insulation properties.
Figure 8. Building thermal insulation global market forecast, by material type

Source: JRC representation with data from Visiongain, 2017.
5 Supply chain of thermal insulation materials and key industrial players

The value chain of the building thermal insulation materials comprises a multi-level network of raw materials suppliers, manufacturers of finished insulation products and distributors to end-users, such as construction companies (Figure 9).

Figure 9. Supply chain of thermal insulation materials used in building applications

Different raw materials (i.e. fibreglass, synthetic minerals, metal oxides, Styrofoam, etc.) are required for production of building insulation products. The raw materials determine the final properties of insulation products, for instance, water resistance, temperature range, durability, compressive strength, etc. Depending on climate conditions and level of insulation to be reached, different products are required in various forms, shapes and sizes to suit a variety of building insulation applications such as flat/pitch roof, internal/external walls and floors.

The competitive intensity of the global building insulation market was estimated from different perspectives using the Porter’s five forces, namely: competitive rivalry, bargaining power of suppliers, the threat of new entrants, bargaining power of buyers and availability of substitutes (Figure 10).

Figure 10. Porter’s five forces analysis in global building thermal insulation market

Source: JRC representation with data from Visiongain, 2017.
According to Visiongain, the five competitive forces for the global building thermal insulation market could be defined as follows (Visiongain, 2017):

- **Competitive rivalry within the global industry**
  Due to a large number of suppliers in the building insulation market, the global market is moderately competitive. Despite the growing rate expected for the building insulation market in the next 10 years, the high product differentiation offered by major players could slow down the competition in the market.

- **Threat of new entrants**
  The capital required for opening new production facilities for thermal insulation materials is very high. The available technologies are often protected; therefore a new entrant must either develop a new process or buy the licence of the technology from an incumbent or outside source. This might result in higher production cost of building insulation materials as compared to competitors, resulting in low economy of scale. Therefore, the threat of new entrant is evaluated as low to moderate.

- **Bargaining power of suppliers**
  In general, there is a low differentiation in the price of building insulation materials offered by most market suppliers, although some major producers have developed low cost manufacturing processes. The high quality of products required in the building insulation is limited, increasing the bargaining power of suppliers. The bargaining power of suppliers is considered moderate, which can be further reduced as a consequence of backward integration.

- **Threat of substitutes**
  Wool insulation minerals and plastic foams account together for more than 90% of the overall insulation material market due to their cost, vast availability and good insulation performance. Other materials such as wood fibre and perlite are also used despite their higher price. Low production cost is desired in the building and construction sector due to their direct interface with customers. Low R&D investments and lack of skilled manpower represent some barriers in development of alternative substitutes for insulation materials. Their low availability and higher production cost make the potential substitutes uneconomical for the end use industry. Therefore, the threat of substitutes is low.

- **Bargaining power of buyers**
  A large number of buyers are active and most of them perusing backward integration, resulting in the high bargaining power of buyers.

The top 10 global companies producing thermal insulation products are: BASF SE (Germany), Beijing New Building Material (Group) Co. Ltd. (China), GAF (USA), Johns Manville (USA), Kingspan Group (Ireland), Knauf Insulation (Germany), Owens Corning Corporation (USA), Paroc (Finland), Rockwool International (Denmark) and Saint Gobain (France). **Six out of the 10 major manufacturers of building insulation materials are European companies.** These key EU companies provide together a complete range of insulation materials for buildings applications and are major producers of one or two of them (Table 1). For example, Rockwool group produces only mineral wool, but is the world leader of stone wool insulation products.

Source: JRC compilation with information from Visiongain, 2017.

There are many other large companies and SMEs in the EU that manufacture and supply materials for insulating residential and non-residential buildings, both new or being renovated. For example, the polyurethane (PUR/PIR) insulation industry in the EU involves about 61,800 companies, providing 258,000 jobs and generating an economic value of EUR 42.2 billion (PU Europe, 2017).

Overall, the global competitive landscape for thermal insulation materials is considered not highly competitive. An annual compound growth rate of 4.5% is expected between 2016 and 2027 for building thermal insulations, which will stimulate the industry competition in the global market. The large product differentiation offered by the European companies and the growth strategies adopted by them in the last 5 years, such as geographic and capacity expansions, new product launches and acquisitions, place them in a good position in the global market of buildings thermal insulations. Therefore, the current competitive rivalry from other non-EU companies or countries could be considered to be low to moderate. This conclusion is also supported by the SWOT analysis of the major European companies operating in the insulation materials industrial sector (Figure 11).

Figure 11. SWOT analysis of the EU industry of thermal insulation materials

6 Advanced insulation materials for building envelopes — an opportunity for industrial innovation

Europe is a leader in innovation for deep renovation of buildings and has the potential to become an export market of these new techniques (e.g. prefabricated systems) in the future.

There are various innovation opportunities for improving a building envelope through developing advanced materials for renovation, for example, super insulating materials (SIM), phase change materials, etc. These opportunities will be driven in principal by the increasing insulation thickness requirements as well as consumer demand/preferences, manufacturer choice, prices and resources.

Although the new super insulating materials, such as vacuum insulation panels, gas-filled panels and aerogel-based products provide promising solutions, the manufacturers still remain focussed on conventional insulation materials, which have the large market value.
7 Conclusions

The European insulation materials industry has a key role in reducing the environment impact of buildings and maximising their energy efficiency by providing the materials needed in the insulation of the building envelope. In the recent years, the EU has made progress in adopting policies for promoting the renovation of Europe's building stock and preventing heat gain/loss though insulation. These measures are expected to boost both the construction sector and EU market of buildings insulation materials: in the period 2015-2027, the EU market is expected to increase at a GAGR of 3.48%.

Wool insulation materials (glass and stone wool) and plastic foams (EPS, XPS, PUR) are the most common type of materials currently used in building applications. Due to the good thermal properties, fire safety, versatility and life span, wool insulation is most widely used for building insulation. However, the plastic foam insulation segment is projected to increase much faster by 2027 due to their products’ better insulation properties.

Currently, the EU represents the largest market of buildings insulation materials globally in terms of value, closely followed by North America, Asia-Pacific and South America. Several key producers of these materials are located in the EU; six out of the top 10 manufacturers are European companies. Some of them are also world leader of insulation products (e.g. stone wool). Overall, the EU is a net exporter of insulation materials. With many others companies acting in different steps of the value chain of insulation products, the current supply of insulation materials could be considered as sustainable.

The competitiveness of the European industry of thermal insulation materials for building applications in relation to other international competitors is considered moderate to strong. However, such competitiveness can be affected by growing demand rate and quality standards of insulating products. This can result in rising manufacturing costs, in the context of requirements for better building insulation and reconfiguration of the European construction industry. Europe should preserve its leadership in innovation for deep renovation of buildings and thermal insulation products. Additionally, there is a need to invest in research for development of smart solutions (e.g. reflective coatings, phase change materials, etc.) and advanced materials with super insulating properties.
