Abstract

The aim of this paper is to study the distribution of portfolio returns across portfolios and for given asset returns. We focus on the most common type of investment considering portfolios whose weights are non-negative and sum up to 1. We provide algorithms and formulas from computational geometry and the literature on splines to compute the exact values of the probability density function, and of the cumulative distribution function at any point. We also provide closed-form solutions for the computation of its first four moments, and an algorithm to compute the higher moments. All algorithms and formulas allow for equal asset returns.

Keywords: Cross-section of portfolios, Finance, Geometry, B-spline

1 Introduction

The study of the distribution of portfolio returns, across portfolios and for given asset returns, has attracted less attention than it deserves in the finance

\textsuperscript{*}The views expressed are those of the authors and do not necessarily reflect official positions of the European Commission.
literature. However it is a natural tool to understand the relative performance of portfolios, as well as the behavior of asset cross-section and market dynamics in general. Indeed, consider an investment set defined as the set of portfolios in which a manager can invest. The most common is such that the portfolio weights are non-negative and sum up to 1. Let us define the score of a portfolio as the percentage of portfolios, within the investment set, that this portfolio outperforms. For instance, in a market of 3 assets whose returns are 0%, 1% and 1.5%, the score of a portfolio as a function of its return is as given in Figure 1. Here, a portfolio whose return is 0.866% outperforms 50% of the portfolios.

![Figure 1: Score of a long-only portfolio in a market of 3 assets whose returns are 0%, 1% and 1.5%](image)

This portfolio score has been introduced in [Pouchkarev, 2005] and has been used in related studies by the same author: In [Pouchkarev, 2005, Pouchkarev et al., 2004, Hallerbach et al., 2002], the relative performance of value-weighted indices with respect to long-only portfolios is assessed in the Dutch, Spanish and German markets. It leads the authors to question the representativeness of these indices. In [Hallerbach and Pouchkarev, 2005, Hallerbach and Pouchkarev, 2016], the dispersion of the cross-sectional portfolio returns is used to assess the performance of asset managers whose mandate implies

---

1It corresponds to the long-only strategy.

2through the MSCI Netherlands 24, IBEX 35, and DAX 30 components, respectively.
tracking error volatility constraints. This score has also been proposed independently in [Billio et al., 2011], and in [Banerjee and Hung, 2011]. In [Billio et al., 2011], this score is used as a portfolio performance measure whose informativeness is shown to be higher than the Sharpe and Sortino ratios in an asset allocation exercise. In [Banerjee and Hung, 2011], a simplified score assigning a reward ranging from -2 to 2 according to the quintile of the score is used to assess the performance of the momentum strategy. This investment strategy is shown to not be outperforming an uninformed naive investor. Recently, in [Càles et al., 2018], the score is used to study the time-varying dependency of portfolios’ return and volatility, and relates this dependency to periods of financial turmoils.

In terms of computation, [Pouchkarev, 2005, Theorem 4.2.2] proposes a geometry-based closed form expression of the score. It consists in representing the long only investment set as a simplex. The score is then the volume of the intersection of the simplex and a halfspace. It is computed by decomposing this intersection in smaller simplices. However, this approach is not valid when some asset returns are equal. As a consequence, in [Pouchkarev, 2005] and in related studies, the score is estimated by a quasi-Monte Carlo sampling of the portfolios as described in [Rubinstein and Melamed, 1998]. In [Banerjee and Hung, 2011, Theorem A2], the same approach is considered for illustration purposes only, and the authors also rely on portfolio sampling for their application. In [Billio et al., 2011], the set of portfolios considered is the specific set of long/short equally weighted zero-dollar portfolios. The estimation of the score relies on combinatorics and order statistics, and it is computationally limited to around 20 assets. Finally, in [Càles et al., 2018], the score is also computed as the volume of the intersection of the simplex and a linear half-space. The authors noticed that an algorithm by [Varsi, 1973] can be used to compute this volume exactly and efficiently for any number of assets, even when some asset returns are equal.

In this paper, we intend to characterize statistically the distribution of the portfolios’ returns, the score being its cumulative distribution function (CDF). We provide algorithms and formulas to compute exactly its CDF, its probability density function (PDF) and its moments. We consider the most common investment set, i.e. the set of portfolios whose weights are non-negative and sum up to 1. In Section 2, we formalize the representation

\footnote{Note that the formula proposed contains a couple of mistakes: the sum is over the number of assets whose returns are lower than the return of the portfolio considered, and the term within parenthesis in the numerator should be the opposite.}
of this set as a unit simplex. The portfolios considered are then uniformly distributed over this simplex, allowing us to integrate over it, later on.

In Section 3, we first recall the computation of the CDF as proposed in [Cales et al., 2018]. The set portfolios having same total return is a hyperplane, hence the question consists in computing the volume of the intersection of a simplex and a linear half-space. Based on equivalent results by [Varsi, 1973] using a geometric approach, and [Ali, 1973] with a divided differences approach, the algorithm consists in a recurrence formula. We also propose its computation with a closed-form formula by [Lasserre, 2015] and [Cales, 2019] which considers the case of equal asset returns, as opposed to [Pouchkarev, 2005] and [Banerjee and Hung, 2011]. Next, we compute exactly the PDF.

The first approach is based on the geometric interpretation of univariate B-splines by Curry and Schoenberg, 1966, and it uses the de Boor-Cox recursive formula, see [de Boor, 1972] and [Cox, 1972]. The second approach is a direct derivation of the CDF obtained using the closed-form formula by [Lasserre, 2015]. Finally, since these two approaches suffer of numerical instability in high dimensions, we propose to derive it numerically from Varsi’s results.

In Section 4, we derive the moments of the distribution. Our method is based on a result by [Lasserre and Avrachenkov, 2001] which provides an elegant way to integrate symmetric q-linear forms on a simplex. It allows us to propose closed-form solutions for the first four moments, and an algorithm to compute higher moments.

2 Geometric representation of the set of portfolios

In this section we formalize the geometric representation of sets of portfolios with an arbitrary number of assets.

Let us consider a portfolio \( x \) investing in \( n \) assets, whose weights are \( x = (x_1, \ldots, x_n) \). The portfolios in which a long-only asset manager can invest are subject to \( \sum_{i=1}^{n} x_i = 1 \) and \( x_i \geq 0, \forall i \). Thus, the set of portfolios available to this asset manager is the unit \((n-1)\)-simplex, denoted \( \Delta^{n-1} \) and defined as

\[
\Delta^{n-1} = \left\{ \sum_{i=1}^{n} x_i v_i \ \bigg| (x_1, \ldots, x_n) \in \mathbb{R}^n, \sum_{i=1}^{n} x_i = 1 \text{ and } x_i \geq 0, \forall i \in \{1, \ldots, n\} \right\}
\]
where \( v_1, \ldots, v_n \in \mathbb{R}^{n-1} \) are a set of \( n \) affinely independent points in a Euclidean space of dimension \( n - 1 \). The vertices \((v_i)_{i=1,\ldots,n}\) represent the \( n \) portfolios made of a single asset and the simplex is the convex hull of these vertices.

For instance, we can define \( v_1, \ldots, v_n \) such that:

1. the center of the simplex is set to the origin,
2. the distances of the simplex vertices to its center are equal,
3. the angle subtended by any two vertices through its center is \( \arccos\left(\frac{-1}{n-1}\right) \).

The weights \((x_i)_{i=1,\ldots,n}\) of portfolio \( x \) are called its barycentric coordinates, whereas in \( \mathbb{R}^{n-1} \) they are called its Cartesian coordinates and are denoted by \( \tilde{x} = (\tilde{x}_1, \ldots, \tilde{x}_{n-1}) \). We use the Cartesian coordinates in Section 4 to compute the moments of the portfolios’ returns distribution.

### 3 PDF and CDF of the portfolios’ returns distribution

In this section we focus on the exact computation of the cumulative distribution function (CDF) and of the probability density function (PDF) of the portfolio returns, given the asset returns.

#### 3.1 The CDF of the portfolios’ returns distribution

Let us consider the set of long-only portfolios providing a return lower than a given return \( R^* \) over a period of time for which the asset returns were \( R = (R_1, \ldots, R_n) \). It corresponds to a linear half-space defined as

\[
H(R^*) = \left\{ (x_1, \ldots, x_n) \in \mathbb{R}^n \mid \sum_{i=1}^{n} R_i x_i \leq R^* \right\}.
\]  

(2)

Denoting by \( V(A) \) the volume of a geometric object \( A \), the allocation score of a portfolio providing a return \( R^* \) can be obtained by computing the ratio of the volume of the intersection of the simplex with this half-space over the volume of the simplex, i.e.

\[
S(R^*) = \frac{V(H(R^*) \cap \Delta^{n-1})}{V(\Delta^{n-1})}.
\]  

(3)
We illustrate such a volume in Figure 2. Consider a market of 4 assets whose returns are observed, and a portfolio providing a given return $R^*$. The pyramid is the simplex representing the set of long-only portfolios. The surface highlighted in the left figure represents the set of portfolios returning $R^*$. The volume highlighted in the right figure represents the set of portfolios providing a return lower or equal to $R^*$.

3.1.1 Varsi’s algorithm

As noticed in Calès et al., 2018, there exists an exact, iterative formula for the volume defined by intersecting a simplex with a half-space. It is provided in Algorithm 1. A geometric proof is given in Varsi, 1973, by subdividing the polytope into pyramids and, recursively, to simplices. For a comparison between alternative proofs and algorithms, the reader may refer to Calès et al., 2018 and the references thereof.

Algorithm 1. Let $H = \{(\omega_1, \ldots, \omega_n) \mid \sum_{i=1}^{n} R_i \omega_i \leq R^*\}$ be a linear half-space.

1. Compute $u_i = R_i - R^*$, $i = 1, 2, \ldots, n$.
2. Label the non-negative $u_j$ as $Y_1, \ldots, Y_K$ and the negative ones as $X_1, \ldots, X_J$.
3. Initialize $A_0 = 1$, $A_1 = A_2 = \cdots = A_K = 0$.
4. For $h = 1, 2, \ldots, J$ repeat: $A_k = \frac{Y_k A_k - X_k A_{k-1}}{Y_k - X_k}$, for $k = 1, 2, \ldots, K$. 

Figure 2: (left) Surface of portfolios providing this given return. (right) Volume of portfolios outperformed by this return.
Then, for $h = J$, $A_K = \frac{V(H(R^*) \cap \Delta_{n-1})}{V(\Delta_{n-1})}$.

This algorithm requires $O(n^2)$ operations, and thus can be computed very quickly. As an illustration, we compute the score of a portfolio whose return is 0 in markets of 100, 1000 and 10,000 assets whose returns are randomly drawn from a centered normal distribution. The computation is repeated 1000 times. We report in Table 1 the average computation time and its standard deviation.

Table 1: Mean computation time in seconds and standard deviation of the computation of the CDF at a point for markets of 100, 1000 and 10,000 assets. The computations have been performed using Matlab© on a bi-xeon E2620 v3 under Windows©.

To illustrate the CDF obtained using Algorithm 1, let us consider a market of 10 assets whose returns are as in Table 2 and let $R^*$ denote a portfolio return. The CDF of the portfolios returns for any given return is reported in Figure 3. With these asset returns, 10% of the portfolios have a negative return and a bit more than 20% of the portfolios have a return greater than 1%.

### 3.1.2 Closed form expression

In [Lasserre, 2015], a closed form formula is proposed to compute this volume taking into account the case of equal asset returns. However, it omitted some extra terms and has been corrected in [Calès, 2019]. We report it here, adapted to our notation: Let $\mathbf{R} = (R_i)_{i=1}^n$ be the asset returns, $(S_i)_{i=1}^d$ the $d$ distinct returns, where $d \leq n$, and $(m_i)_{i=1}^d$ their multiplicities (i.e. number of occurrences). We denote by $(J_i)_{i=1}^d$ the subsets of indices in $\{1, \ldots, n\}$ associated to each $S_i$ and,

$$
\text{for } j = 1, \ldots, d, \text{ we let } b_j = \left( \frac{1}{R_i - S_j} \right)_{i \in \{1, \ldots, n\} \setminus J_j}.
$$
Among the distinct returns we distinguish between those whose multiplicities are 1, and those whose multiplicities are greater than 1. The indices of the first group form a set denoted by $I$, while those of the second group form set $K$, where $S = I \cup K$. Finally, $(x)_{+}$ stands for $\max\{0, x\}$. The CDF computed in $R^*$ is given by:

$$S(R^*, R) = \sum_{i \in I} \frac{(R^* - S_i)_+^{n-1}}{\prod_{j=1, j \neq i} (S_j - S_i)} +$$

$$+ \sum_{i \in K} \left( \sum_{j=0}^{m_i-1} (-1)^{j+m_i+1} \binom{n-1}{j} \frac{(R^* - S_i)^{n-j-1}}{\prod_{k \in S \setminus \{S_i\}} (S_k - S_i)} \Phi_{m_i-1-j}(b_i) \right),$$

with

$$\Phi_k(x) = \sum_{i_1=1}^{n} \sum_{i_2=1}^{i_1} \cdots \sum_{i_k=1}^{i_{k-1}} x_{i_1} \cdots x_{i_k}, \ x \in \mathbb{R}^n.$$  

This formula is similar to the one proposed in [Pouchkarev, 2005 Theorem 4.2.2] and [Banerjee and Hung, 2011 Theorem A2], but with extra terms correcting for the equal asset returns. Unfortunately, when it comes to calculations, the formula becomes numerically unstable for $n \geq 20$ at the usual machine precision.

### 3.1.3 Properties of the score

As noticed in [Banerjee and Hung, 2011], the score is invariant under some linear transformation of the asset returns. To see this, let us consider a market
of $n$ assets providing the returns $\mathbf{R} = (R_i)_{i=1}^n$. We are interested in the score of a portfolio $\omega = (\omega_i)_{i=1}^n$ providing a return $R^* = \omega' \mathbf{R}$, where $\omega'$ stands for the transpose vector. As explained before, this score is the volume of simplex $\Delta^{n-1}$ intersected with half-space $H(R^*)$ as in Equation (2). So, it is

$$S(R^* | \mathbf{R}) = \left\{ \theta \in \Delta^{n-1} \left| \sum_{i=1}^n R_i \theta_i \leq R^* \right. \right\}$$

(5)

**Property 1.** The score is invariant under linear transformations of the asset returns such that $\mathbf{R} \rightarrow \sigma \mathbf{R} + \alpha$ with $\alpha \in \mathbb{R}$ and $\sigma \in \mathbb{R}^+$. 

*Proof.*

$$S(\sigma R^* + \alpha | \sigma \mathbf{R} + \alpha) = \left\{ \theta \in \Delta^{n-1} \left| \sum_{i=1}^n (\sigma R_i + \alpha) \theta_i \leq \sigma R^* + \alpha \right. \right\}$$

$$= \left\{ \theta \in \Delta^{n-1} \left| \sigma \sum_{i=1}^n R_i \theta_i + \alpha \leq \sigma R^* + \alpha \right. \right\}$$

$$= \left\{ \theta \in \Delta^{n-1} \left| \sigma \sum_{i=1}^n R_i \theta_i \leq \sigma R^* \right. \right\}$$

$$= S(R^* | \mathbf{R}).$$

The main implication of this property is that the asset returns can be standardized cross-sectionally without affecting the score. It is interesting to note that such a transformation is common in financial event studies, since the seminal work of [Boehmer et al., 1991]. This approach has the advantages of being robust to event-induced heteroskedasticity and of not requiring data from a pre-event estimation period.

### 3.2 The PDF of the portfolios’ returns distribution

In this section we focus on the exact computation of the probability density function (PDF) of the portfolios’ returns distribution.

#### 3.2.1 Geometric interpretation of B-splines

In [Curry and Schoenberg, 1966], a seminal paper on splines, Theorem 2 shows that the univariate B-spline resulting from the orthogonal projection of the volumetric slices of a unit simplex on $\mathbb{R}$ can be interpreted as the PDF of these slices’ volume. For instance, in Figure 4, we have the projections
of the areas of the intersection of planes with the 3-d simplex on the real line. In our case, the simplex is the set of portfolios, while the planes are the equi-return portfolios. The resulting univariate B-spline is the PDF of the portfolio returns. For any value, it can be computed using the de Boor-Cox recursion formula, see [de Boor, 1972] and [Cox, 1972], as shown in Algorithm 2.

Algorithm 2. Let $\mathbf{R} = (R_i)_{i=1}^n$ be the returns of the $n$ assets, ordered such that $R_i \leq R_j$ for $i < j$, and let $k = n - 1$ be the B-spline order. To evaluate the PDF at $x$, we set $j = 1$ and call function $\text{bspline_pdf}(\cdot)$ as defined below. The outcome is then normalized such that $y = y k \frac{k^{k - 1}}{\pi_{n-1}}$.

function $y = \text{bspline_pdf}(j,k,R,x)$

1. $y = 0$
2. if $k > 1$ then

Figure 4: Geometric interpretation of the PDF of the portfolio returns: a univariate B-spline, as the orthogonal projection of the volumetric slices of a unit simplex on $\mathbb{R}$. In this example, we have 4 assets whose returns are 0%, 1%, 1.5% and 2%.
(a) \( b = \text{bspline}_{\text{pdf}}(j, k-1, R, x); \)

(b) if \( R_{j+k} \neq R_{j+1} \), then \( y = y + b \left( \frac{x-R_{j+1}}{R_{j+k}-R_{j+1}} \right) \)

(c) \( b = \text{bspline}_{\text{pdf}}(j+1, k-1, R, x); \)

(d) if \( R_{j+k+1} \neq R_{j+2} \), then \( y = y + b \left( \frac{R_{j+k+1}-x}{R_{j+k+1}-R_{j+2}} \right) \)

3. elseif \( R_{j+1} \leq x \)

(a) if \( R_{j+2} < R_n \) and \( x < R_{j+2} \), then \( y = 1 \), else \( y = 0 \)

4. else

(a) if \( R_{j+1} \leq x \) and \( R_{j+2} > R_n \), then \( y = 1 \), else \( y = 0 \)

</tbody>
</table>

Table 3: Mean computation time in seconds and standard deviation of the computation of the PDF at a point for markets of 10 and 20 assets. The computations have been performed using Matlab® on a bi-xeon E2620 v3 under Windows®.

As an illustration, let us consider the previous example with 10 assets. Using Algorithm 2, we compute the PDF of the portfolios’ returns and report it in Figure 5. In this example, we observe that the distribution is uni-modal with most portfolios having a return close to 0.6%. In the next section, we shall focus on the computation of the moments of this distribution.

3.2.2 Closed form expression

It is straightforward to get the PDF by deriving Equation (4). Using the same notation as in Section 3.1.2, this leads to the following closed-form formula for the PDF:

\[

c(R^*, R) = (n - 1) \sum_{i \in I} \frac{(R^* - S_i)_{+}^{n-2}}{\prod_{j=1, j \neq i} (S_j - S_i)} + \\
\sum_{i \in K} \left( \sum_{j=0}^{m_i-1} (-1)^{j+m_i+1} (n - j - 1) \binom{n-1}{j} \frac{(R^* - S_i)_{+}^{n-j-2}}{\prod_{k \in S_i \setminus S_i} (S_k - S_i)} \Phi_{m_i-1-j}(b_i) \right).
\]

\[ (6) \]

Its computation suffers from the same drawback as the computation of the CDF, providing numerically unstable results for \( n \geq 20 \) at the usual machine precision.
3.2.3 Numerical derivation

The iterative nature of the de Boor-Cox formula makes the computation of the PDF slow for large number of assets, say $\geq 20$. Moreover, its computation using the closed form formula above is numerically unstable for large number of assets, say $\geq 20$. So, a practical alternative is to estimate the PDF by deriving numerically the CDF obtained earlier, using Varsi’s algorithm.

Let $F$ be the CDF and $x_0$ the point in which we wish to estimate its derivative. One may employ central differences and the five points’ method, thus having

$$F'(x_0) = \frac{-F(x_0 + 2h) + 8F(x_0 + h) - 8F(x_0 - h) + F(x_0 - 2h)}{12h} + \frac{h^4}{30} F^{(5)}(c),$$

with $c \in [x_0 - 2h, x_0 + 2h]$. The truncation error is then $O(h^4)$. Even though it is only an estimate of the PDF, this approach enables us to scale up to thousands of assets with computation times being 5 times higher than those reported in Table 1 for an estimate at a single point with the five points method.

4 Moments of the portfolios’ returns distribution

In this section, we compute the moments of the portfolios returns. In Section 4.1 we provide affine maps to pass from barycentric to Cartesian coor-
4.1 Barycentric and Cartesian representations

There are affine maps to pass

- from barycentric to Cartesian coordinates:
  \[ m_{bc} : \mathbb{R}^n \to \mathbb{R}^{n-1}, \quad x \mapsto \bar{x} = Tx + v_n, \]  
  where vertices \( v_i \) correspond to \((n - 1)\)-dimensional column vectors, and \( T = [v_1 - v_n, \ldots, v_{n-1} - v_n] \) is an \((n - 1) \times (n - 1)\) matrix.

- from Cartesian to barycentric coordinates:
  \[ m_{cb} : \mathbb{R}^{n-1} \to \mathbb{R}^n, \quad \bar{x} \mapsto x = \left[ I_{n-1} -1'_{n-1} \right] T^{-1}(\bar{x} - v_n) + \left[ 0_{n-1} 1 \right], \]  
  where \( 0_{n-1} \) and \( 1_{n-1} \) are the \((n - 1)\)-dimensional column vectors of 0’s and 1’s, respectively, and \( I_{n-1} \) is the \((n - 1) \times (n - 1)\) identity matrix.

The return of portfolio \( x \) is then given by
  \[ R'x = A\bar{x} - Av_n + R_n, \]  
  where \( A = R'\left[ I_{n-1}' -1_{n-1}' \right] T^{-1} \). By construction, we also have these useful identities:

**Lemma 2.** For \( n \in \mathbb{N} \), vertices \( (v_i)_{i=1}^n \), and matrix \( A \) as defined previously, it holds
  \[ \sum_{i=1}^n Av_i = A \sum_{i=1}^n v_i = 0. \]
Lemma 3. For \( n \in \mathbb{N} \), \((R_i)_{i=1}^n\), \((v_i)_{i=1}^n\), \(A\) and \(M_1\) as defined previously, it holds
\[
R_i = Av_i - Av_n + R_n, \ i \in \{1, \ldots, n\}.
\] (12)

Lemma 4. For \( n \in \mathbb{N} \), \((R_i)_{i=1}^n\), \((v_i)_{i=1}^n\), \(A\) and \(M_1\) as defined previously, it holds
\[
M_1 = R_n - Av_n.
\] (13)

Lemma 5. For \( n \in \mathbb{N} \), \((R_i)_{i=1}^n\), \((v_i)_{i=1}^n\), \(A\) and \(M_1\) as defined previously, it holds
\[
Av_i = R_i - M_1.
\] (14)

4.2 Moments

We are interested in the distribution of the portfolio returns given the observed individual asset returns \( R = (R_1, \ldots, R_n) \).

By definition, the moments of the portfolio returns distribution are given as follows, where \( V(\cdot) \) stands for Euclidean volume:
\[
M_1 = \frac{1}{V(\Delta^{n-1})} \int_{\Delta^{n-1}} (Ax - Av_n + R_n) \, d\vec{x},
\] (15)
\[
M_2 = \frac{1}{V(\Delta^{n-1})} \int_{\Delta^{n-1}} (Ax - Av_n + R_n - M_1)^2 \, d\vec{x},
\] (16)
\[
M_k = \frac{1}{V(\Delta^{n-1})(\sqrt{M_2})^k} \int_{\Delta^{n-1}} (Ax - Av_n + R_n - M_1)^k \, d\vec{x}, \ k \geq 3,
\] (17)

where the term \( \frac{1}{V(\Delta^{n-1})} \) is normalizing the equations. Indeed, the distance between the vertices \( v_i \) is arbitrary, and so is the volume of \( \Delta^{n-1} \). An alternative is to choose the distance between the vertices \( v_i \) such that \( V(\Delta^{n-1}) = 1 \).

By employing Lemma 4, \( M_2 \) and \( M_k \) simplify to
\[
M_2 = \frac{1}{V(\Delta^{n-1})} \int_{\Delta^{n-1}} (Ax)^2 \, d\vec{x},
\] (18)
\[
M_k = \frac{1}{V(\Delta^{n-1})(\sqrt{M_2})^k} \int_{\Delta^{n-1}} (Ax)^k \, d\vec{x}, \ k \geq 3.
\] (19)
4.3 Integrating over \( \Delta^{n-1} \)

From [Lasserre and Avrachenkov, 2001], and slightly adapted to our notations, we have the following

**Theorem 6.** Let \( v_1, \ldots, v_n \) be the vertices of an \((n−1)\)-dimensional simplex \( \Delta^{n-1} \). Then, for a symmetric \( q \)-linear form \( H: (\mathbb{R}^{n-1})^q \to \mathbb{R} \), we have

\[
\int_{\Delta^{n-1}} H(X, \ldots, X) \, d\hat{x} = \frac{V(\Delta^{n-1})}{(n-1+q)\binom{n+q}{q}} \sum_{1 \leq i_1 \leq i_2 \leq \cdots \leq i_q \leq n} H(v_{i_1}, v_{i_2}, \ldots, v_{i_q}),
\]

(20)

where \( V(\Delta^{n-1}) \) stands for the volume of the simplex \( \Delta^{n-1} \).

4.4 Nested sum identities

In the following, we employ these identities:

**Lemma 7.** For \( n \in \mathbb{N} \), it holds

\[
2 \sum_{i=1}^{n} \sum_{j=i}^{n} x_i x_j = \left( \sum_{i=1}^{n} x_i \right)^2 + \sum_{i=1}^{n} x_i^2.
\]

(21)

**Proof.** Trivial.

**Lemma 8.** For \( n \in \mathbb{N} \), it holds

\[
(3!) \sum_{i=1}^{n} \sum_{j=i}^{n} \sum_{k=j}^{n} x_i x_j x_k = \left( \sum_{i=1}^{n} x_i \right)^3 + 3 \left( \sum_{i=1}^{n} x_i \right) \left( \sum_{i=1}^{n} x_i^2 \right) + 2 \sum_{i=1}^{n} x_i^3.
\]

(22)

See proof in Annex A.

**Lemma 9.** For \( n \in \mathbb{N} \), it holds

\[
(4!) \sum_{i=1}^{n} \sum_{j=i}^{n} \sum_{k=j}^{n} \sum_{l=k}^{n} x_i x_j x_k x_l =
\]

\[
= \left( \sum_{i=1}^{n} x_i \right)^4 + 6 \left( \sum_{i=1}^{n} x_i \right)^2 \left( \sum_{i=1}^{n} x_i^2 \right) + 8 \left( \sum_{i=1}^{n} x_i \right) \left( \sum_{i=1}^{n} x_i^3 \right) + 6 \left( \sum_{i=1}^{n} x_i^4 \right) + 3 \left( \sum_{i=1}^{n} x_i^2 \right)^2.
\]

See proof in Annex B.
4.5 Expression of moments’ individual terms

We now need to compute \( \int_{\Delta^{n-1}} (A\hat{x})^p \, d\hat{x} \), where \( p \) corresponds to a single term of the development.

**Lemma 10.** For \( n \in \mathbb{N} \), it holds

\[
\int_{\Delta^{n-1}} (A\hat{x})^2 \, d\hat{x} = \frac{V(\Delta^{n-1})}{n(n+1)} \sum_{i=1}^{n} (Av_i)^2.
\]  

(23)

**Proof.** Apply Theorem 6 with \( q = 2 \), and \( H(\hat{x}_1, \hat{y}_2) = (A\hat{x}_1)(A\hat{x}_2) \), by replacing the nested sum in the theorem as in Lemma 7, then recalling Lemma 2.

**Lemma 11.** For \( n \in \mathbb{N} \), it holds

\[
\int_{\Delta^{n-1}} (A\hat{x})^3 \, d\hat{x} = \frac{2V(\Delta^{n-1})}{n(n+1)(n+2)} \sum_{i=1}^{n} (Av_i)^3.
\]

(24)

**Proof.** Apply Theorem 6 with \( q = 3 \), and \( H(\hat{x}_1, \hat{y}_2, \hat{y}_3) = (A\hat{x}_1)(A\hat{x}_2)(A\hat{x}_3) \), by replacing the nested sum in the theorem as in Lemma 8, then recalling Lemma 2.

**Lemma 12.** For \( n \in \mathbb{N} \), it holds

\[
\int_{\Delta^{n-1}} (A\hat{x})^4 \, d\hat{x} = \frac{V(\Delta^{n-1})}{n(n+1)(n+2)(n+3)} \left( 6 \left( \sum_{i=1}^{n} (Av_i)^4 \right) + 3 \left( \sum_{i=1}^{n} (Av_i)^2 \right)^2 \right).
\]

**Proof.** Apply Theorem 6 with \( q = 4 \), and \( H(\hat{x}_1, \hat{y}_2, \hat{y}_3, \hat{y}_4) = (A\hat{x}_1)(A\hat{x}_2)(A\hat{x}_3)(A\hat{x}_4) \), replacing the nested sum in the theorem as in Lemma 9, then recalling Lemma 2.

4.6 Closed form expression of the first four moments

In this section, we derive the following closed form expressions for the first four moments, reported in Theorems 13 to 16, respectively.

**Theorem 13.** In a market of \( n \) assets, \( n \in \mathbb{N} \), whose returns are \( \mathbf{R} = (R_i)_{i=1}^{n} \), the first moment of the portfolios’ returns is

\[
M_1 = \frac{1}{n} \sum_{i=1}^{n} R_i.
\]

(25)
Proof. See proof in Annex C.

Theorem 14. In a market of \( n \) assets, \( n \in \mathbb{N} \), whose returns are \( \mathbf{R} = (R_i)_{i=1}^n \), the second moment of the portfolios’ returns is

\[
M_2 = \frac{1}{n(n+1)} \sum_{i=1}^n (R_i - M_1)^2 = \frac{1}{n+1} \text{Var}(\mathbf{R}), \tag{26}
\]

where \( \text{Var} \) is the biased sample variance.

Proof. Replace \( \int_{\Delta^{n-1}} (A\hat{x})^2 \, d\hat{x} \) in Equation (18) by the expression from Lemma 10, then apply Lemma 5.

Theorem 15. In a market of \( n \) assets, \( n \in \mathbb{N} \), whose returns are \( \mathbf{R} = (R_i)_{i=1}^n \), the third moment of the portfolios’ returns is

\[
M_3 = \frac{1}{M_2^{3/2} n(n+1)(n+2)} \sum_{i=1}^n (R_i - M_1)^3. \tag{27}
\]

Proof. By replacing \( \int_{\Delta^{n-1}} (A\hat{x})^3 \, d\hat{x} \) in Equation (19) with the expression from Lemma 11 and applying Lemma 5, one obtains the result.

Theorem 16. In a market of \( n \) assets, \( n \in \mathbb{N} \), whose returns are \( \mathbf{R} = (R_i)_{i=1}^n \), the fourth moment of the portfolios’ returns is

\[
M_4 = \frac{1}{M_2^2 n(n+1)(n+2)(n+3)} \left( 6 \sum_{i=1}^n (R_i - M_1)^4 + 3 \left( \sum_{i=1}^n (R_i - M_1)^2 \right)^2 \right). \tag{28}
\]

Proof. By replacing \( \int_{\Delta^{n-1}} (A\hat{x})^4 \, d\hat{x} \) in Equation (19) with the expression from Lemma 12 and applying Lemma 5, the claim is established.

4.7 General algorithm to compute the moments

We now wish to compute the \( k^{th} \) moment of the portfolios’ returns, i.e., restating Equation (19), we compute

\[
M_k = \frac{1}{\text{Vol}(\Delta^{n-1}) (\sqrt{M_2})^k} \int_{\Delta^{n-1}} (A\hat{x})^k \, d\hat{x}, \quad k \geq 3.
\]
Let us set $H(X_1, \ldots, X_k) = \prod_{i=1}^{k} X_i$. It is a symmetric $k$-linear form, and we have

$$H(A\vec{x}, \ldots, A\vec{x}) = (A\vec{x})^k.$$  

Thus from Theorem 6 we have

$$\int_{\Delta^{n-1}} H(A\vec{x}, \ldots, A\vec{x}) \, d\vec{x} = \frac{V(\Delta^{n-1})}{n - 1 + k} \sum_{1 \leq m_1 \leq m_2 \leq \cdots \leq m_k \leq n} H(Av_{m_1}, Av_{m_2}, \ldots, Av_{m_k}).$$

Let $q_i$ be the number of occurrences of value $i$, $1 \leq i \leq n$. Then,

$$\int_{\Delta^{n-1}} (A\vec{x})^k \, d\vec{x} = \frac{V(\Delta^{n-1})}{n - 1 + k} \sum_{n_{q_i=1}}^{n} \prod_{i=1}^{d} (Av_i)^{q_i}.$$

Now, we change the notations. Let $\lambda = (\lambda_1, \ldots, \lambda_k)$ be a partition of $k$, and $\Lambda_k$ the set of partitions of $k$. We denote by $l = (l_i)_{i=1}^{d}$ the $d$ unique non-zero values in $\lambda$, $d \leq k$, and by $(p_i)_{i=1}^{d}$ the multiplicities of $(l_i)_{i=1}^{d}$. For instance, $\lambda = (2, 1, 1, 0)$ is a partition of $k = 4$, with $d = 2$, $l = (1, 2)$ and the associated multiplicities $p = (2, 1)$.

From [Macdonald, 1995, Eq. (2.14')], we have

$$\sum_{n_{q_i=1}}^{n} \prod_{i=1}^{d} (Av_i)^{q_i} = \sum_{\lambda \in \Lambda_k} \frac{\prod_{i=1}^{d} \left( \sum_{j=1}^{n} (Av_j)^{l_i} \right)^{p_i}}{\prod_{i=1}^{d} p_i! q_i^{p_i}}.$$

Set $\Lambda_k$ can be obtained with Algorithm ZS1 in [Zoghbi and Stojmenovic, 1994], and is still tractable for large moments, as shown on Table 4:

<table>
<thead>
<tr>
<th>$k$</th>
<th>1</th>
<th>5</th>
<th>10</th>
<th>20</th>
<th>30</th>
<th>40</th>

<td>627</td>
<td>5604</td>
</tr>
</tbody>
</table>

Table 4: Number of partitions $|\Lambda_k|$ for different values of $k$.

The computation is formally presented in Algorithm 3. As an illustration of the computation times, we compute the $k$th order moments, $k = 5, 10, 15, 20$, for markets of 100, 1000 and 10,000 assets whose returns are randomly drawn. The computation is repeated 1000 times. We report in Table 5 the average computation time in seconds and its standard deviation.
Algorithm 3. Let $R$ be the asset returns, $N$ the number of assets, and $k$ the moment order.

1. Compute $M_2$ by Theorem 14
2. Compute $A_v$ as in Lemma 5
3. Compute $\Lambda$ using Algorithm ZS1 in [Zoghbi and Stojmenovic, 1994]
4. Set $S = 0$
5. For each $\lambda \in \Lambda$:
   (a) decompose $\lambda$ in its $d$ non-zero elements $(l_i)_{i=1}^d$ with multiplicities $(p_i)_{i=1}^d$
   (b) $a = \prod_{i=1}^d p_i! l_i^{p_i}$
   (c) $b = \prod_{i=1}^d \left( \sum_{j=1}^n (A_v)_{ij} \right)^{p_i}$
   (d) $S = S + a/b$
6. Set $M_k = S / \left( \sqrt{M_2^k \cdot \binom{n-1+k}{k}} \right)$

Table 5: Mean runtime in seconds, and standard deviation in parenthesis, of computing the moment of order $k$ in markets of 100, 1000 and 10,000 assets. The assets returns are drawn randomly before each of the 1000 computations. The experiments were performed with Matlab© on a bi-xeon E2620 v3 under Windows©.
5 Concluding remarks and future work

In this paper, we reviewed different approaches to compute the PDF, CDF and moments of the distribution of portfolio returns, across portfolios and for the long-only strategy.

For the CDF, the computations improve upon existing work by providing exact results, allowing for equal asset returns, and handle a large number of assets, thus removing the need of Monte Carlo sampling for its estimation. These computations can be based on:

- the volume algorithm by [Varsi, 1973] which is fast and exact even for a large number of assets,
- the closed form expression of CDF, which is exact but numerically unstable for a large number of assets.

For the PDF, our methods are new, based on what follows:

- the algorithm by de Boor and Cox [de Boor, 1972, Cox, 1972], which is exact but slow for a large number of assets,
- the closed form expression of PDF, which is exact but numerically unstable for a large number of assets,
- the numerical derivation of the CDF using [Varsi, 1973], which only provides an estimate but is fast and applies to a large number of assets.

For the moments, the computations are new and can based on

- closed form expressions up to the fourth-order moment,
- a new algorithm using Algorithm ZS1 by [Zoghbi and Stojmenovic, 1994], for higher moments, which is fast and exact even for a large number of assets.

It should be noted that most of these computations can easily be vectorized, thus further extending their realm of applications.

These results have several statistical and econometric implications.

- The asset returns can be standardized cross-sectionally without altering the relative performance of portfolios. The series obtained are then robust to systemic heteroskedasticity.
The closed form expressions of the first three moments show a direct mapping between the moments of the cross-sectional asset returns distribution and those of the distribution of portfolio returns.

In particular, the first moments are identical for both distributions. The second and third moments are proportional to each other, the factor depending on the number of assets. For the second moment, the factor is \( \frac{1}{N+1} \) where \( N \) is the number of assets, implying that it might be more difficult to find a portfolio which performs significantly better than the equally weighted portfolio, when the number of assets increases.

The closed form expression of the fourth moment behaves differently with an extra positive term implying fatter tails in the distribution of portfolio returns than in the cross-sectional distribution of the asset returns. Its implications have to be further analyzed.

The relevance of computing high moments can be discussed. We believe that these moments should be useful in an alternative method recovering the PDF. Indeed, since the distribution is bounded, this problem is known as the Hausdorff moment problem, which has been addressed, see for instance [Mnatsakanov, 2008]. This approach has been inconclusive for the authors.

Future work can take several directions. On the theoretical side, it would be interesting to study the distribution of portfolio volatilities in order to better assess the dependency between portfolios returns and volatilities, which is done by sampling in [Caïès et al., 2018] It would also be interesting to consider different investment sets, e.g. including short selling\(^4\) and leverage\(^5\).

In terms of applications, it should be noticed that the paper focuses on portfolio returns but the methodology can be applied to any linear combination of asset characteristics, e.g. by defining the portfolio dividend yield as the weighted sum of the asset dividend yields. The use of the score, i.e., the CDF, has already found applications in portfolio performance measures. These may be improved, for instance by considering the random nature of the asset returns. The PDF can be used to finely assess the distribution of portfolios with possible applications in portfolio diversification and turnover analysis.

The moments can find applications in the literature on return dispersion, see e.g. [Yu and Sharaiha, 2007], [Stivers and Sun, 2010], [Gorman et al., 2010], [Bhootra, 2011] and [Verousis and Voukelatos, 2018]. They can also find applications in the literature on noise trading, see e.g. [De Long et al., 1989].

\(^4\)i.e. negative portfolio weights.

\(^5\)i.e. sum of portfolio weights greater than one.

A Proof of Lemma 8

Lemma 8 For $n \in \mathbb{N}$, it holds

$$6 \sum_{i=1}^{n} \sum_{j=i}^{n} \sum_{k=j}^{n} x_i x_j x_k = \left( \sum_{i=1}^{n} x_i \right)^3 + 3 \left( \sum_{i=1}^{n} x_i \right) \left( \sum_{i=1}^{n} x_i^2 \right) + 2 \sum_{i=1}^{n} x_i^3.$$

Proof. Let $S(n) = \sum_{i=1}^{n} \sum_{j=i}^{n} \sum_{k=j}^{n} x_i x_j x_k$. The cases $n = 0$ and $n = 1$ are easily verifiable. Let us assume that the theorem holds for $S(n), n \geq 1$. We shall prove it for $S(n+1)$. Clearly,

$$S(n+1) = S(n) + \sum_{i=1}^{n} \sum_{j=i}^{n} \sum_{k=j}^{n} x_i x_j x_{n+1} + \sum_{i=1}^{n} x_i x_{n+1}^2 + x_{n+1}^3,$$

which, by inductive hypothesis, yields

$$6S(n+1) = \left( \sum_{i=1}^{n} x_i \right)^3 + 3 \left( \sum_{i=1}^{n} x_i \right) \left( \sum_{i=1}^{n} x_i^2 \right) + 2 \sum_{i=1}^{n} x_i^3 + 6x_{n+1} \sum_{i=1}^{n} \sum_{j=i}^{n} x_i x_j + 6x_{n+1}^2 \sum_{i=1}^{n} x_i + 6x_{n+1}^3.$$

The underlined term becomes

$$3x_{n+1} \left( 2 \sum_{i=1}^{n} x_i^2 + 2 \sum_{i=1}^{n} \sum_{j>i} x_i x_j \right), \quad (29)$$

where the last index $j$ is strictly larger than $i$. The overall sum is re-written as the sum of the following three terms, where we have underlined terms corresponding to sum (29):

$$\left( \sum_{i=1}^{n} x_i \right)^3 + 3x_{n+1} \left( \sum_{i=1}^{n} x_i \right)^2 + 3x_{n+1}^2 \sum_{i=1}^{n} x_i + x_{n+1}^3 = \left( \sum_{i=1}^{n} x_i + x_{n+1} \right)^3,$$

$$3 \left[ \left( \sum_{i=1}^{n} x_i \right) \left( \sum_{i=1}^{n} x_i^2 \right) + x_{n+1} \sum_{i=1}^{n} x_i^2 + x_{n+1}^2 \sum_{i=1}^{n} x_i + x_{n+1}^3 \right] =$$

$$= 3 \left( \sum_{i=1}^{n} x_i + x_{n+1} \right) \left( \sum_{i=1}^{n} x_i^2 + x_{n+1}^2 \right),$$

$$2 \sum_{i=1}^{n} x_i^3 + 2x_{n+1}^3,$$

which correspond to the three sums of the original claim.
B Proof of Lemma 9

Lemma 9 For \( n \in \mathbb{N} \), it holds

\[
(4!) \sum_{i=1}^{n} \sum_{j=i}^{n} \sum_{k=j}^{n} \sum_{l=k}^{n} x_i x_j x_k x_l =
\]

\[
= \left( \sum_{i=1}^{n} x_i \right)^4 + 6 \left( \sum_{i=1}^{n} x_i \right)^2 \left( \sum_{i=1}^{n} x_i^2 \right) + 8 \left( \sum_{i=1}^{n} x_i \right) \left( \sum_{i=1}^{n} x_i^3 \right) + 6 \left( \sum_{i=1}^{n} x_i^4 \right) + 3 \left( \sum_{i=1}^{n} x_i^2 \right)^2
\]

Proof. Let \( S(n) = \sum_{i=1}^{n} \sum_{j=i}^{n} \sum_{k=j}^{n} x_i x_j x_k x_l \). The cases \( n = 0 \) and \( n = 1 \) are easily verifiable. Let us assume that the theorem holds for \( S(n) \), \( n \geq 1 \). We shall prove it for \( S(n+1) \). Clearly,

\[
S(n+1) = S(n) + \sum_{i=1}^{n} \sum_{j=i}^{n} \sum_{k=j}^{n} x_i x_j x_k x_{n+1} + \sum_{i=1}^{n} \sum_{j=i}^{n} x_i x_j x_{n+1}^2 + \sum_{i=1}^{n} x_i x_{n+1}^3 + x_{n+1}^4,
\]

which, by the inductive hypothesis, yields:

\[
24S(n+1) =
\]

\[
= \left( \sum_{i=1}^{n} x_i \right)^4 + 6 \left( \sum_{i=1}^{n} x_i \right)^2 \left( \sum_{i=1}^{n} x_i^2 \right) + 8 \left( \sum_{i=1}^{n} x_i \right) \left( \sum_{i=1}^{n} x_i^3 \right) + 6 \left( \sum_{i=1}^{n} x_i^4 \right) + 3 \left( \sum_{i=1}^{n} x_i^2 \right)^2
\]

\[
+ 24x_{n+1} \sum_{i=1}^{n} \sum_{j=i}^{n} \sum_{k=j}^{n} x_i x_j x_k + 24x_{n+1}^2 \sum_{i=1}^{n} \sum_{j=i}^{n} x_i x_j + 24x_{n+1}^3 \sum_{i=1}^{n} x_i + 24x_{n+1}^4.
\]

Let \( A = x_{n+1}^3 \sum_{i=1}^{n} x_i \) and \( B = x_{n+1}^4 \). From Lemma 8 we have

\[
24x_{n+1} \sum_{i=1}^{n} \sum_{j=i}^{n} \sum_{k=j}^{n} x_i x_j x_k =
\]

\[
= 4x_{n+1} \left( \sum_{i=1}^{n} x_i \right)^3 + 3 \left( \sum_{i=1}^{n} x_i \right) \left( \sum_{i=1}^{n} x_i^2 \right) + 2 \left( \sum_{i=1}^{n} x_i^3 \right)
\]

\[
= 4x_{n+1} \left( \sum_{i=1}^{n} x_i \right)^3 + 12x_{n+1} \left( \sum_{i=1}^{n} x_i \right) \left( \sum_{i=1}^{n} x_i^2 \right) + 8x_{n+1} \sum_{i=1}^{n} x_i^3
\]

\[
= C + D + E
\]

28
And from Lemma 8, we have

\[ 24x_{n+1}^2 \sum_{i=1}^{n} \sum_{j=1}^{n} x_i x_j = -12x_{n+1}^2 \left( \sum_{i=1}^{n} x_i \right)^2 + \sum_{i=1}^{n} x_i^2 \]
\[ = 12x_{n+1}^2 \left( \sum_{i=1}^{n} x_i \right)^2 + 12x_{n+1}^2 \left( \sum_{i=1}^{n} x_i^2 \right). \]

The overall sum is rewritten using the sum of the following four terms:

\[ \left( \sum_{i=1}^{n+1} x_i \right)^4 = \left( \sum_{i=1}^{n} x_i \right)^4 + 4x_{n+1} \left( \sum_{i=1}^{n} x_i \right)^3 + 6x_{n+1}^2 \left( \sum_{i=1}^{n} x_i \right)^2 + 4x_{n+1}^3 \left( \sum_{i=1}^{n} x_i \right) + x_{n+1}^4. \]
\[ 6 \left( \left( \sum_{i=1}^{n+1} x_i \right)^2 \left( \sum_{i=1}^{n} x_i^2 \right) \right) = 6 \left( \left( \sum_{i=1}^{n} x_i \right)^2 + 2x_{n+1} \left( \sum_{i=1}^{n} x_i \right) + x_{n+1}^2 \right) \left( x_{n+1}^2 + \sum_{i=1}^{n} x_i^2 \right) \]
\[ = 6 \left( \sum_{i=1}^{n} x_i \right)^2 \left( \sum_{i=1}^{n} x_i^2 \right) + 6x_{n+1}^2 \left( \sum_{i=1}^{n} x_i \right)^2 + 12x_{n+1}^3 \left( \sum_{i=1}^{n} x_i \right) + \sum_{i=1}^{n} x_i^4. \]
\[ 8 \left( \sum_{i=1}^{n+1} x_i \right) \left( \sum_{i=1}^{n+1} x_i^3 \right) = 8 \left( \sum_{i=1}^{n} x_i \right) \left( \sum_{i=1}^{n} x_i^3 \right) + 8x_{n+1} \left( \sum_{i=1}^{n} x_i^3 \right) + 8x_{n+1}^3 \left( \sum_{i=1}^{n} x_i \right) + 8x_{n+1}^4. \]
\[ 3 \left( \sum_{i=1}^{n+1} x_i^2 \right)^2 = 3 \left( \sum_{i=1}^{n} x_i^2 \right)^2 + 6x_{n+1}^2 \left( \sum_{i=1}^{n} x_i^2 \right) + 3x_{n+1}^4. \]
C Proof of Theorem \textbf{13}

By definition of the second moment in Eq. \textbf{15} we have

$$V(\Delta^{n-1}) M_1 = \int_{\Delta^{n-1}} A\ddot{x} - Av_n + R_n \, d\ddot{x} = \int_{\Delta^{n-1}} A\ddot{x} \, d\ddot{x} + (-Av_n + R_n) V(\Delta^{n-1}).$$

From Lemma \textbf{9} and simplifying by $V(\Delta^{n-1})$, we get

$$M_1 = \left(\frac{1}{n} \sum_{i=1}^{n} Av_i\right) + (-Av_n + R_n)$$

$$= \frac{1}{n} \sum_{i=1}^{n} (Av_i - Av_n + R_n) = \frac{1}{n} \sum_{i=1}^{n} R_i,$$

which concludes the proof.
GETTING IN TOUCH WITH THE EU

In person
All over the European Union there are hundreds of Europe Direct information centres. You can find the address of the centre nearest you at: https://europa.eu/european-union/contact_en

On the phone or by email
Europe Direct is a service that answers your questions about the European Union. You can contact this service:
- by freephone: 00 800 6 7 8 9 10 11 (certain operators may charge for these calls),
- at the following standard number: +32 22999696, or
- by electronic mail via: https://europa.eu/european-union/contact_en

FINDING INFORMATION ABOUT THE EU

Online
Information about the European Union in all the official languages of the EU is available on the Europa website at: https://europa.eu/european-union/index_en

EU publications
You can download or order free and priced EU publications from EU Bookshop at: https://publications.europa.eu/en/publications. Multiple copies of free publications may be obtained by contacting Europe Direct or your local information centre (see https://europa.eu/european-union/contact_en).
The European Commission’s science and knowledge service
Joint Research Centre

JRC Mission
As the science and knowledge service of the European Commission, the Joint Research Centre’s mission is to support EU policies with independent evidence throughout the whole policy cycle.
